```

Lip cancer

Here is the lip cancer data given to you in terribly unreproducible and error-prone format.

- aff.i is proportion of male population working outside in each region
- observe.i is observed deaths in each region
- expect.i is expected deaths, based on region-specific age distribution and national-level age-specific mortality rates.

```
observe.i <- c(

Question 1

Explain a bit more what the expect.i variable is. For example, if a particular area has an expected deaths of 6, what does this mean?

Answer

Expected deaths is the implied number of lip cancer deaths for a particular region given that region's age structure and the national level age-specific mortality rates for lip cancer. For example, an expected number of deaths of 6 would mean that for that particular region we would expect 6 lip cancer deaths if this region were to experience the same age-specific mortality rates as at the national level.

Question 2

Run three different models in Stan with three different set-up's for estimating θ_i , that is the relative risk of lip cancer in each region:

- 1. Intercept α_i is same in each region = α
- 2. α_i is different in each region and modeled separately (with covariate)
- 3. α_i is different in each region and the intercept is modeled hierarchically (with covariate)

Answer

$$y_i|\theta \sim \text{Poisson}(\theta_i \cdot e_i)$$

Look at three models for $\log \theta_i$:

1.

$$\log \theta_i = \alpha + \beta x_i$$

2.

$$\log \theta_i = \alpha_i + \beta x_i$$

3.

$$\log \theta_i = \alpha_i + \beta x_i \quad \alpha_i \sim N(\mu, \sigma^2)$$

```
mod2 <- stan(data = stan_data, file = "lab9_2.stan")
# Run model 3
mod3 <- stan(data = stan_data, file = "lab9_3.stan")</pre>
```

Question 3

Make two plots (appropriately labeled and described) that illustrate the differences in estimated θ_i 's across regions and the differences in θ s across models.

Uncertainty around model 2 is bigger since we are adding more parameters (each alpha is different).

```
res_mod1 <- mod1 |>
  gather_draws(log_theta[i]) |>
  median_qi() |>
  rename(median_mod1 = .value,
         lower_mod1 = .lower,
         upper_mod1=.upper) |>
  select(i, median_mod1:upper_mod1)
res_mod2 <-mod2 |>
  gather_draws(log_theta[i]) |>
  median_qi() |>
  rename(median_mod2 = .value,
         lower_mod2 = .lower,
         upper_mod2=.upper) |>
  select(i, median_mod2:upper_mod2)
res_mod3 <- mod3 |>
  gather_draws(log_theta[i]) |>
  median_qi() |>
  rename(median_mod3 = .value,
         lower_mod3 = .lower,
         upper_mod3=.upper) |>
  select(i, median_mod3:upper_mod3)
res <- res_mod1 |> left_join(res_mod2) |> left_join(res_mod3)
```

```
res |> select(median_mod1, median_mod2, median_mod3) |>
   pivot_longer(median_mod1:median_mod3, names_to = "model", values_to = "log_theta") |> m
   ggplot(aes(log_theta, fill = model)) + geom_histogram(position = "dodge")
```

```
res |> mutate(deaths = observe.i, log_smr = log(observe.i/expect.i)) |>
    ggplot(aes(log_smr, median_mod1, color = "Model 1")) + geom_point(
    aes(size = deaths)) +
    geom_errorbar(aes(ymin = lower_mod1, ymax = upper_mod1))+ geom_abline(slope =1, intercept geom_point(aes(log_smr, median_mod2, color = "Model 2"))+
        geom_errorbar(aes(ymin = lower_mod2, ymax = upper_mod2, color = "Model 2")) +
        geom_point(aes(log_smr, median_mod3, color = "Model 3"))+
        geom_errorbar(aes(ymin = lower_mod3, ymax = upper_mod3, color = "Model 3"))
```
